THE LIFE CYCLE OF A PASSIVE TREATMENT SYSTEM:
A STUDY OF THE OPEN LIMESTONE CHANNEL AT SOVERN RUN #
62

J. Brady Gutta and Paul Ziemkiewicz

Abstract: Limestone has long been the single most cost effective treatment in
efforts to combat acid mine drainage. Over time, the constant degradation and
inundation by iron sludge reduces the limestone’s ability to neutralize the mine
drainage. In September of 2003, a reworking of the open limestone channel at
Sovern Run #62 was performed to increase the channel’s ability to raise the pH,
generate alkalinity, and precipitate metals. We will discuss the life cycle from the
channel’s initial installation to present day. Aspects including cost, performance,
and the chemical parameters such as acidity, alkalinity, pH and metal
concentrations will be examined.

1Paper was presented at the 2004 National Meeting of the American Society of Mining and
Reclamation and The 25th West Virginia Surface Mine Drainage Task Force, April 18 – 24,
2004. Published by ASMR, 3134 Montavesta Road, Lexington, KY 40502.
