PHOSPHORUS FERTILIZER RATE AND EXTRACTABLE PHOSPHORUS ON A RECLAIMED AND UNDISTURBED PASTURE SOIL\(^1\)

Josh Hall\(^2\), John Winslow\(^2\), and Louis M. McDonald\(^3\)

**Abstract.** Reclaimed surface mine soils are sufficiently different from the native, undisturbed soils that they may require a different fertilizer management strategy to maintain forage productivity. Two top soils were collected from North Central West Virginia, one from a reclaimed surface mine and one from an adjacent, undisturbed pasture. Soils were air-dried and lightly crushed to pass a 2mm sieve. Inorganic phosphorus as KH\(_2\)PO\(_4\) was added at five different rates to both soils (three replications) and then subjected to repeated wetting and drying cycles at 32-34\(^\circ\)C in a dark growth chamber. Mehlich 3 and CaCl\(_2\) extractable phosphorus was determined after the last drying. Extractable phosphorus was lower in the reclaimed mine soil, suggesting that additional fertilizer phosphorus would be needed for adequate forage production.
